Computational Structures in Data Science

Lecture 7

Abstract Data Types

October 21, 2019 <http://cs88.org>

1

Computational Concepts Toolbox

- Data type: values, literals, operations,
 - e.g., int, float, string
- Expressions, Call expression
- Variables
- Assignment Statement
- Sequences: tuple, list
 - indexing
- Data structures
- Tuple assignment
- Call Expressions
- Function Definition Statement
- Conditional Statement
- Iteration:
 - data-driven (list comprehension)
 - control-driven (for statement)
 - while statement
- Higher Order Functions
 - Functions as Values
 - Functions with functions as argument
 - Assignment of function values
- Recursion
- Lambda - function valued expressions

10/21/19 UCB CS88 Fa19 L7

2

Announcements

- Midterm Tonight!
- Monday 10/21 7-9pm, 155 Dwinelle
- 1 page, double-sided handwritten cheat sheet

10/21/19 UCB CS88 Fa19 L7

3

Today's Lecture

- Abstract Data Types
 - More use of functions!
 - Value in documentation and clarity
- New Python Data Types
 - Dictionaries, a really useful tool!

10/21/19 UCB CS88 Fa19 L7

4

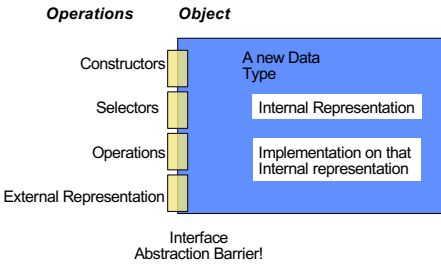

Why ADTs?

- “Self-Documenting”
 - `contact_name(contact)`
 - » Vs `contact[0]`
 - “0” may seem clear now, but what about in a week? 3 months?
- Change your implementation
 - Maybe today it's just a Python List
 - Tomorrow: It could be a file on your computer; a database in web

10/21/19 UCB CS88 Fa19 L7

5

Abstract Data Type

Operations Object

Constructors A new Data Type

Selectors Internal Representation

Operations Implementation on that Internal representation

External Representation

Interface
Abstraction Barrier!

10/21/19 UCB CS88 Fa19 L7

6

Creating Abstractions

- Compound values combine other values together
 - date: a year, a month, and a day
 - geographic position: latitude and longitude
- Data abstraction lets us manipulate compound values as units
- Isolate two parts of any program that uses data:
 - How data are represented (as parts)
 - How data are manipulated (as units)
- Data abstraction: A methodology by which functions enforce an abstraction barrier between *representation* and *use*

7

Reminder: Lists

- Lists
 - Constructors:
 - » `list(...)`
 - » `[<expr>, ...]`
 - » `[<exp> for <var> in <list> [if <exp>]]`
 - Selectors: `<list> [<index or slice>]`
 - Operations: `in`, `not in`, `+`, `*`, `len`, `min`, `max`
 - » Mutable ones too (but not yet)

8

A Small ADT

```
def point(x, y): # constructor
    return [x, y]

x = lambda point: point[0] # selector
y = lambda point: point[1]

def distance(p1, p2): # Operator
    return ((x(p2) - x(p1))**2 + (y(p2) - y(p1))**2) ** 0.5

origin = point(0, 0)
my_house = point(5, 5)
campus = point(25, 25)
distance_to_campus = distance(my_house, campus)
```

9

Creating an Abstract Data Type

- Constructors & Selectors
- Operations
 - Express the behavior of objects, invariants, etc
 - Implemented (abstractly) in terms of Constructors and Selectors for the object
- Representation
 - Implement the structure of the object
- An *abstraction barrier violation* occurs when a part of the program that can use the higher level functions uses lower level ones instead
 - At either layer of abstraction
- Abstraction barriers make programs easier to get right, maintain, and modify
 - Few changes when representation changes

10

Clicker ? : Changing Representations?

Assuming we update our selectors, what are valid representations for our `point(x, y)` ADT?

Currently `point(1, 2)` is represented as `[1, 2]`

- A) `[y, x]` # `[2, 1]`
- B) `"X: " + str(x) + " Y: " + str(y)`
`"X: 1 Y: 2"`
- C) `str(x) + " " + str(y)` # `"1 2"`
- D) All of the above
- E) None of the above

11

An Abstract Data Type: Key-Value Pair

- Collection of key-Value bindings
 - Key : Value
- Many real-world examples
 - Dictionary, Directory, Phone book, Course Schedule, Facebook Friends, Movie listings, ...

Given some Key, What is the value associated with it?

12

Key-Value ADT

- **Constructors**
 - kv_empty: create an empty KV
 - kv_add: add a key:value binding to a KV
 - kv_create: create a KV from a list of key,value tuples
- **Selectors**
 - kv_items: list of (key,value) tuple in KV
 - kv_keys: list of keys in KV
 - kv_values: list of values in KV
- **Operations**
 - kv_len: number of bindings
 - kv_in: presence of a binding with a key
 - kv_display: external representation of KV

10/21/19

UCB CS88 Fa19 L7

13

13

A little application

```
phone_book_data = [
    ("Christine Strauch", "510-842-9235"),
    ("Frances Catal Bulcan", "932-567-3241"),
    ("Jack Chow", "617-547-0923"),
    ("Joy De Rosario", "310-912-6483"),
    ("Casey Casem", "415-432-9292"),
    ("Lydia Lu", "707-341-1254")
]

phone_book = pb_create(phone_book_data)

print("Jack Chows's Number: ", pb_get(phone_book, "Jack Chow"))

print("Area codes")
area_codes = list(map(lambda x:x[0:3], pb_numbers(phone_book)))
print(area_codes)
```

10/21/19

UCB CS88 Fa19

14

14

A Layered Design Process

- Build the application based entirely on the ADT interface
 - Operations, Constructors and Selectors
- Build the operations in ADT on Constructors and Selectors
 - Not the implementation representation
- Build the constructors and selectors on some concrete representation

10/21/19

UCB CS88 Fa19 L7

15

15

Example 1

- KV represented as list of (key, value) pairs

10/21/19

UCB CS88 Fa19 L7

16

16

Dictionaries

- Lists, Tuples, Strings, Range
- Dictionaries
 - Constructors:
 - » dict(<list of 2-tuples>)
 - » dict(<key>=<val>, ...) # like kwargs
 - » { <key exp>:<val exp>, ... }
 - » { <key>:<val> for <iteration expression> }
 - Selectors: <dict> [<key>]
 - » <dict>.keys(), .items(), .values()
 - » <dict>.get(key [, default])
 - Operations:
 - » Key in, not in, len, min, max
 - » <dict>[<key>] = <val>

10/21/19

UCB CS88 Fa19 L7

17

17

Dictionary Example

```
In [1]: text = "Once upon a time"
        d = {word : len(word) for word in text.split()}

Out[1]: {'Once': 4, 'a': 1, 'time': 4, 'upon': 4}

In [2]: d['Once']

Out[2]: 4

In [3]: d.items()

Out[3]: [('a', 1), ('time', 4), ('upon', 4), ('Once', 4)]

In [4]: for (k,v) in d.items():
        print(k, ">=", v)

('a', '>=', 1)
('time', '>=', 4)
('upon', '>=', 4)
('Once', '>=', 4)

In [5]: d.keys()

Out[5]: ['a', 'time', 'upon', 'Once']

In [6]: d.values()

Out[6]: [1, 4, 4, 4]
```

10/21/19

18

18

Clicker ?: Dictionaries

- What is the result of the final expression?

```
my_dict = { 'course': 'CS 88', semester = 'Fall' }
my_dict['semester'] = 'Spring'
```

```
my_dict['semester']
```

- A) 'Fall'
- B) 'Spring'
- C) Error

19

Limitations

- Dictionaries are unordered collections of key-value pairs
- Dictionary keys have two restrictions:
 - A key of a dictionary cannot be a list or a dictionary (or any *mutable type*)
 - Two keys cannot be equal; There can be at most one value for a given key

This first restriction is tied to Python's underlying implementation of dictionaries

The second restriction is part of the dictionary abstraction

If you want to associate multiple values with a key, store them all in a sequence value

20

Beware

- Built-in data type `dict` relies on mutation
 - Clobbers the object, rather than "functional" – creating a new one
- Throws an error if key is not present
- We will learn about mutation shortly

10/21/19

UCB CS88 Fa19 L7

21

21

Example 3

- KV represented as dict

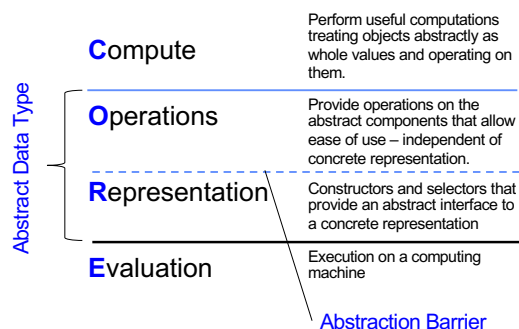

10/21/19

UCB CS88 Fa19 L7

22

23

23

Building Apps over KV ADT

```
friend data = [
  ("Christine Strauch", "Jack Chow"),
  ("Christine Strauch", "Lydia Lu"),
  ("Jack Chow", "Christine Strauch"),
  ("Casey Casem", "Christine Strauch"),
  ("Casey Casem", "Jack Chow"),
  ("Casey Casem", "Frances Catal Bulloan"),
  ("Casey Casem", "Joy De Rosario"),
  ("Casey Casem", "Casey Casem"),
  ("Frances Catal Bulloan", "Jack Chow"),
  ("Jack Chow", "Frances Catal Bulloan"),
  ("Joy De Rosario", "Lydia Lu"),
  ("Joy De Lydia", "Jack Chow")
]
```

- Construct a table of the friend list for each person
